Statistics

July 2018

Stats? There is a package for that!

Package	Models
stats	Generalized linear model
afex	Anovas
lme4	Mixed effects regression
rpart	Decision Trees
BayesFactor	Bayesian statistics
igraph	Network analysis
neuralnet	Neural networks
MatchIt	Matching and causal inference
survival	Longitudinal survival analysis
•••	Anything you can ever want!

In this session...

- 1 Basic structure and arguments of most **statistical functions**
 - formula: Specify your variables
 - data: A data frame containing variables.
- 2 Simple htest objects
 - t.test(), correlation
- 3 (Generalized) linear model
 - lm(), glm(), aov()
- 4 Explore statistical objects
 - MODEL\$NAME, print(), summary(), names(), predict(), plot()
- 5 Conduct simulations

```
# T-test comparing height based on gender
t.test(formula = height ~ sex,
         data = baselers)
# Regression model
inc_glm <- glm(formula = income ~ .,</pre>
                data = baselers %>% select(-id))
# Summary information
summary(inc_glm)
# Dissect
inc_glm$coefficients # Acess coefficients
inc_glm$residuals # Access residuals
### Generate random data
x1 < -rnorm(n = 100, mean = 10, sd = 5)
x2 < -rnorm(n = 100, mean = 5, sd = 1)
noise \leftarrow rnorm(n= 100, mean = 0, sd = 10)
# Create y as a function of x1, x2, and noise
y \leftarrow x1 + x2 + noise
df <- data.frame(x1, x2, y)</pre>
# Regress y on x1 and x2
lm(formula = y \sim .,
   data = df
```

Basic structure of statistical functions

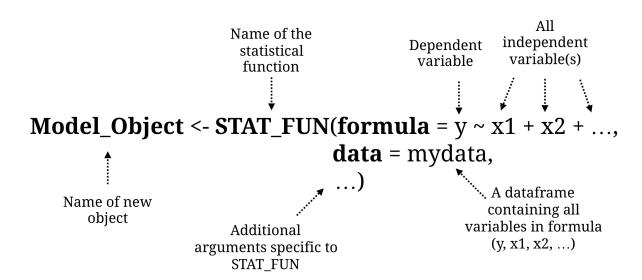

Statistical functions always require a data frame called data, e.g.,...

sex	age	height	weight	income
male	44	174.3	113.4	6300
male	65	180.3	75.2	10900
female	31	168.3	55.5	5100

They also require a **formula** that specifies a **dependent** variable (y) as a function of one or more **independent** variables (x1, x2, ...) in the form:

formula =
$$y \sim x1 + x2 + ...$$

How to create a statistical object:

Look for optional arguments

Statistical functions usually have many optional arguments.

Each of these have **default** values. To customise a test, **look at the help menu** and specify arguments explicitly.

<u>Default vs. customised glm() (Generalized linear model)</u>

```
# Default
glm(formula = income ~ age + education,
    data = baselers)

# Customised
glm(formula = eyecor ~ age + education,
    data = baselers,
    family = "binomial") # Logistic regression
```

Default vs. customised t-test

Look for optional arguments

?glm

```
R Documentation
glm {stats}
Fitting Generalized Linear Models
Description
{\tt glm} is used to fit generalized linear models, specified by giving a symbolic description of the linear predictor and a
glm(formula, family = gaussian, data, weights, subset,
    na.action, start = NULL, etastart, mustart, offset,
control = list(...), model = TRUE, method = "glm.fit",
    x = FALSE, y = TRUE, contrasts = NULL, ...)
glm.fit(x, y, weights = rep(1, nobs),
          start = NULL, etastart = NULL, mustart = NULL,
         offset = rep(0, nobs), family = gaussian(),
          control = list(), intercept = TRUE)
## S3 method for class 'glm'
weights(object, type = c("prior", "working"), ...)
formula an object of class "formula" (or one that can be coerced to that class): a symbolic description of
               the model to be fitted. The details of model specification are given under 'Details'.
             a description of the error distribution and link function to be used in the model. For glm this can be a
               character string naming a family function, a family function or the result of a call to a family function.
              For glm.fit only the third option is supported. (See family for details of family functions.)
              an optional data frame, list or environment (or object coercible by as.data.frame to a data frame)
              containing the variables in the model. If not found in data, the variables are taken from
              environment (formula), typically the environment from which glm is called.
weights an optional vector of 'prior weights' to be used in the fitting process. Should be NULL or a numeric
 subset an optional vector specifying a subset of observations to be used in the fitting process.
```

Default vs. customised glm() (Generalized linear model)

```
# Default
glm(formula = income ~ age + education,
    data = baselers)

# Customised
glm(formula = eyecor ~ age + education,
    data = baselers,
    family = "binomial") # Logistic regression
```

Default vs. customised t-test

Simple hypothesis tests

All of the basic **one and two sample hypothesis tests** are included in the stats package.

These tests take either a **formula** for the argument formula, or **individual vectors** for the arguments x, and y

Hypothesis Test	R Function
T-test	t.test()
Correlation Test	cor.test()
Chi-Square Test	<pre>chisq.test()</pre>

T-Test with t.test()

```
# 1-sample t-test
t.test(x = baselers age,
       mu = 40) # Mean under H0
# 2-sample t-test (Output hidden)
t.test(formula = income ~ sex,
       data = baselers)
##
      One Sample t-test
## data: baselers$age
## t = 28, df = 10000, p-value <2e-16
## alternative hypothesis: true mean is not equal to 40
## 95 percent confidence interval:
## 44.29 44.93
## sample estimates:
## mean of x
       44.61
                                                    7 / 22
```

Simple hypothesis tests

All of the basic **one and two sample hypothesis tests** are included in the stats package.

These tests take either a **formula** for the argument formula, or **individual vectors** for the arguments x, and y

Hypothesis Test	R Function
T-test	t.test()
Correlation Test	cor.test()
Chi-Square Test	<pre>chisq.test()</pre>

Correlation test with cor.test()

```
# Correlation test
cor.test(x = baselers age,
         y = baselers$income)
# Version using formula (same result as above)
cor.test(formula = \sim age + income,
         data = baselers)
##
       Pearson's product-moment correlation
## data: baselers$age and baselers$income
## t = 180, df = 8500, p-value <2e-16
## alternative hypothesis: true correlation is not equal to
## 95 percent confidence interval:
## 0.8882 0.8968
## sample estimates:
     cor
## 0.8926
                                                     8 / 22
```

BaselRBootcamp, July 2018

www.therbootcamp.com

Regression with glm(), lm()

How to **create a regression model** predicting, e.g., how much money people spend on food as a function of income?

Part of the baselers dataframe:

food	income	happiness
610	6300	5
1550	10900	7
720	5100	7
680	4200	7
260	4000	5

Generalized regression with glm()

```
# food (y) on income (x1) and happiness (x2)
food_glm <- glm(formula = food ~ income + happiness,</pre>
               data = baselers)
# Print food_glm
food_glm
## Call: glm(formula = food ~ income + happiness, data = baselers)
## Coefficients:
## (Intercept)
                     income
                               happiness
                      0.101
                                  52.205
      -302.089
## Degrees of Freedom: 8509 Total (i.e. Null); 8507 Residual
    (1490 observations deleted due to missingness)
## Null Deviance:
                         1.27e+09
## Residual Deviance: 6.06e+08
                                   AIC: 119000
                                                                9 / 22
```

Customising formulas

Include additional independent variables to formulas by "adding" them with +

To **include all variables** in a dataframe, use the catch-all notation formula = $y \sim .$

To include interaction terms use x1 : x2 or x1 * x2 (also includes main effects) instead of x1 + x2

Explore statistical objects using **generic** functions such as print(), summary(), predict() and plot().

Generic functions different things depending on the **class label** of the object.

```
# Create a glm object
my_glm <- glm(formula = income ~ happiness + age,
              data = baselers)
# print the my_glm object
print(my_glm)
## Call: glm(formula = income ~ happiness + age, data = baselers)
## Coefficients:
## (Intercept)
                 happiness
                                    age
         1575
                       -100
                                    149
## Degrees of Freedom: 8509 Total (i.e. Null); 8507 Residual
    (1490 observations deleted due to missingness)
## Null Deviance:
                        6.33e+10
## Residual Deviance: 1.28e+10
                                  AIC: 145000
```

```

predict

predict(model, newdata) allows you to use
your model to predict outcomes for newdata.

last_year

id	age	fitness	tattoos	income
1	44	7	6	6300
2	65	8	5	10900

this_year

id	age	fitness	tattoos	income
101	21	3	4	NA
102	23	6	8	NA

Fit model based on leastyear

```
## (Intercept) age tattoos
## 1418.3 145.7 -175.5
```

Now use model to predict values for this year

```
## 1 2
## 3776 3366
```

tidy

The tidy() function from the broom package **converts** the most important results of many statistical object like "glm" to a **data frame**.

```
# install and load broom
install.packages('broom')
library(broom)
```

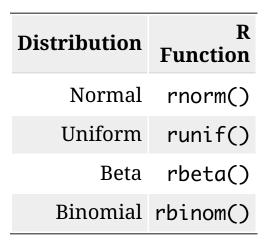

```
# Original printout
my_glm
##
## Call: glm(formula = income ~ happiness + age, data = baselers
##
## Coefficients:
## (Intercept)
                 happiness
                                    age
##
         1575
                      -100
                                    149
## Degrees of Freedom: 8509 Total (i.e. Null); 8507 Residual
    (1490 observations deleted due to missingness)
## Null Deviance:
                        6.33e+10
## Residual Deviance: 1.28e+10
                                  AIC: 145000
# Tidy printout
tidy(my_glm)
##
           term estimate std.error statistic p.value
## 1 (Intercept)

```

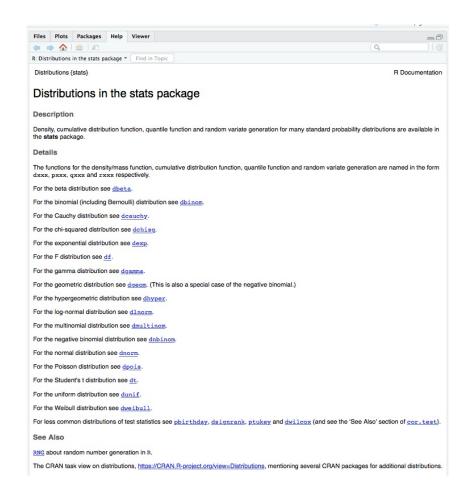

www.therbootcamp.com

Sampling Functions

R gives you a host of functions for sampling data from common **statistical distributions** (see ?distributions).

Use these to easily simulate data:

sample()

Use sample() to draw a random sample from a vector.

The Birthday problem

```
# Create an empty room
birthdays <- c()

# While none of the birthdays are the same,
# keep adding new ones
while(all(!duplicated(birthdays))) {

# Get new birthday
new_day <- sample(x = 1:365, size = 1)

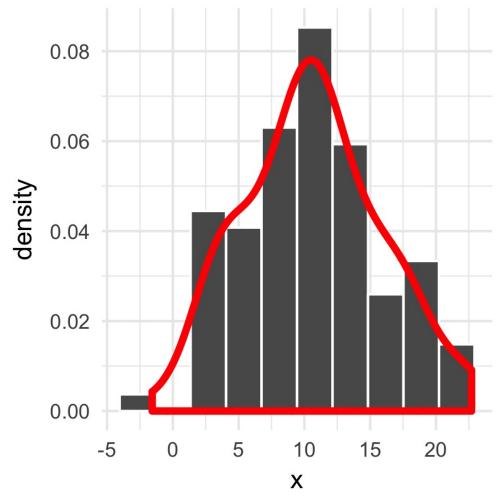

# Add new_day to birthdays
birthdays <- c(birthdays, new_day)
}

# Done! How many are in the room??
length(birthdays)</pre>
```

[1] 25

rnorm, runif(),...

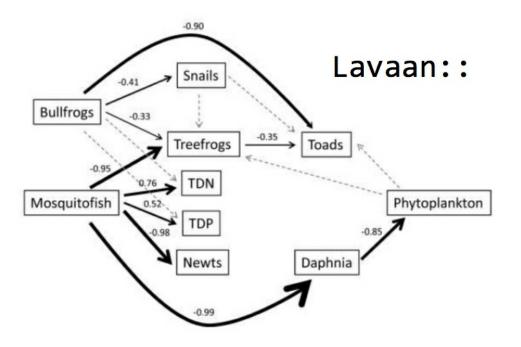

Use the rnorm(), runif(), ... functions to draw random samples from probability distributions.

Other great statistics packages

package	Description
afex	Factorial experiments
lme4	Mixed effects models
rstanarm	Bayesian mixed effects models
BayesFactor	Bayesian Models
forecast	Time series
lavaan	Latent variable and structural equation modelling

Summary

- 1 There are packages for every statistical procedure you can imagine in R.
- 2 Most have **formula** and **data** arguments (among many others).
- 3 Use **help files** to understand the arguments of functions!
- 4 Once you've created a statistical object, use **generic functions** to explore it: print(), names(), summary(), etc.
- 5 Use **random sampling** functions to run simulations.

?t.test

```
t.test {stats}
                                                   R Documentation
Student's t-Test
Description
Performs one and two sample t-tests on vectors of data.
Usage
t.test(x, ...)
## Default S3 method:
t.test(x, y = NULL,
        alternative = c("two.sided", "less", "greater"),
        mu = 0, paired = FALSE, var.equal = FALSE,
       conf.level = 0.95, ...)
## S3 method for class 'formula'
t.test(formula, data, subset, na.action, ...)
Arguments
              a (non-empty) numeric vector of data values.
               an optional (non-empty) numeric vector of data values.
alternative a character string specifying the alternative hypothesis, must
              be one of "two.sided" (default), "greater" or "less".
```
